## 10575 Polylops

Given the vertices of a non-degenerate polygon (no 180-degree angles, zero-length sides, or selfintersection - but not necessarily convex), you must determine how many distinct lines of symmetry exist for that polygon. A line of symmetry is one on which the polygon, when reflected on that line, maps to itself.

## Input

Input consists of a description of several polygons.
Each polygon description consists of two lines. The first contains the integer $n(3 \leq n \leq 1000)$, which gives the number of vertices on the polygon. The second contains $n$ pairs of numbers (an $x$ - and a $y$-value), describing the vertices of the polygon in order. All coordinates are integers from -1000 to 1000.

Input terminates on a polygon with 0 vertices.

## Output

For every polygon described, print out a line saying 'Polygon $\# x$ has $y$ symmetry line(s).', where $x$ is the number of the polygon (starting from 1), and $y$ is the number of distinct symmetry lines on that polygon.

## Sample Input

4
$-1002100-1$
3
$-666-4257-8419282$
3
$-241-5030743-334498$
0

## Sample Output

Polygon \#1 has 1 symmetry line(s).
Polygon \#2 has 0 symmetry line(s).
Polygon \#3 has 1 symmetry line(s).
