# 12948 Interstellar Travel

The Agency for Cross-Constellation and Interstellar Space Travel (ACIS) is ready to offer its clients space travel among several planets across the universe.

ACIS offers a list of flight options consisting of an origin planet, a destination planet, a cost, and a duration. One of the "killer" features ACIS will offer to its clients is that of being able to plan a trip between two planets under the constraint of a maximum number of stops. That is, given a natural number n, ACIS would like to offer each client the cheapest possible trip from an origin planet to a destination planet with at most n stops. Since interstellar in-flight sleep is not pleasant, it is also important to minimize the amount of time spent in a trip.

Can you help ACIS in finding an efficient algorithm for such a task?

### Input

The input consists of several test cases. Each test case begins with a line with three blank-separated integers p, f, and q ( $1 \le p \le 300$ ,  $0 \le f \le 5000$ , and  $0 \le q \le 1000$ ), indicating the number of planets, flights, and queries, respectively. The next p lines each contains a planet name s ( $1 \le |s| \le 30$ ). The next f lines each contains two planet names and two integers  $s_o$ ,  $s_d$ , c, and t (separated by a blank), denoting that there is a direct flight from  $s_o$  to  $s_d$  costing c dollars ( $0 \le c \le 10^5$ ) with a duration of t units of time ( $0 \le t \le 10^5$ ). The next line contains a planet name  $s_i$  indicating the initial planet for the trip. The next q lines each contains a query with a destination planet name  $s_f$  for the trip and a natural number n, both separated by a blank ( $0 \le n \le 300$ ). You can assume that planet names consist only of alphabetic characters, and that  $s_o$ ,  $s_d$ ,  $s_i$ , and  $s_f$  are in the list of p planet names.

#### Output

For each query  $s_i$ ,  $s_f$ , n output two blank-separated integers indicating the minimum cost and the corresponding minimum travel time for this cost of an interstellar trip from  $s_i$  to  $s_f$  with at most n stops. If this is not possible, then print two blank-separated asterisks ('\*').

Print a line with a single period ('.') between consecutive test cases.
