## **12961** Lottery

The lottery BWS is played annually. In this lottery N people bet choosing K numbers each. In a formal way, we can say that  $B_{ij}$  is the j-th value bet by the i-th person. Then the organizers choose K positive integers. The chosen numbers are called  $W_1, W_2, ..., W_K$ .

The winners are calculated as followed:

- A non-empty subset is chosen randomly from the N participants; in other words, some participants are luckily chosen.
- For each person in this subset the value  $S_1$  is calculated, the sum of all the first numbers bet by them, that is, the sum of the  $B_{i1}$  where i is the index of each chosen person. In the same way the values  $S_2$ , ...,  $S_K$  are calculated.
- A parity test between  $W_j$  and  $S_j$  is performed; in other words, it is verified if the parity (if a number is pair or odd) matches between  $W_1$  and  $S_1$ ,  $W_2$  and  $S_2$ , and so on until  $W_K$  and  $S_K$ .
- If all parities match, then the people in this subset are considered the winners!

The organizers want to know: is it possible to pick the numbers  $W_1$ ,  $W_2$ , ...,  $W_K$  so that there is **no** subset of winning participants?

#### Input

The input contains several test cases. The first line of a test case contains the numbers N ( $1 \le N \le 30000$ ) and K ( $3 \le K \le 50$ ), which represent the number of participants and the quantity of numbers bet by each person, respectively. The participants bet with integer numbers between 1 and  $10^9$ , inclusive. Each of the next N lines contains K numbers representing the bet of each person, one person per line.

### Output

For each test case in the input you must output a single line, containing one letter: 'S' in case it is possible or 'N' otherwise.

#### Sample Input

- 2 3
- 1 2 3
- 5 6 7
- 3 3
- 3 2 1
- 6 5 4
- 4 4 4
- 4 3
- 9 4 7
- 4 4 4
- 2 7 2
- 2 2 1
